

Indexing

In this example we create a index on email column , so a database store that column in B-tree datastructure in sorted order and also store the row reference pointer of the main table.

Indexes improve query performance by allowing the database to locate rows faster.

An index is a data structure (usually a B-tree) that speeds up SELECT queries by reducing table scans.

How to create index in prisma

lets look at our user model

```
model User {  
  id      Int      @id @default(autoincrement())  
  email    String   @unique  
  name     String?  
  createdAt DateTime @default(now())  
  
}
```

now suppose we have a function which query user over email, so to fetch user fast its better to create a index on email.

```
model User {  
  id      Int      @id @default(autoincrement())  
  email    String   @unique  
  name     String?  
  createdAt DateTime @default(now())  
  
  @@index([email])  
  
}
```

prisma use @@index annotation to create index, we provide the column in array on which we want to create index.

```
//SQL query to create index, we provide index_name  
CREATE INDEX index_user_email //index name  
ON User(email)
```
