

# What is prisma

## Next-generation Node.js and TypeScript ORM

Prisma ORM unlocks a new level of **developer experience** when working with databases thanks to its intuitive data model, automated migrations, type-safety & auto-completion.

### 1. Data model

In a single file, define your schema. What it looks like, what tables you have, what field each table has, how are rows related to each other.

```
schema.prisma

1 datasource db {
2   provider = "postgresql"
3   url      = env("DATABASE_URL")
4 }
5
6 model Post {
7   id        Int @id @default(autoincrement())
8   title     String
9   content   String?
10  published Boolean @default(false)
11  author     User? @relation(fields: [authorId], references: [id])
12  authorId   Int?
13 }
14
15 model User {
16   id        Int @id @default(autoincrement())
17   email     String @unique
18   name      String?
```

[Check out an example schema](#)

## 2. Automated migration

Prisma generates and runs database migrations based on changes to the Prisma schema. All the changes in schema are stored by prisma in migration history.

As project grows, we added body and title in Post Table.

Migrations are automatically generated so you don't have to write the SQL by hand.

## 3. Type-safe and auto-completion

Prisma generates a type-safe database client based on the Prisma schema.
